Maurice Garcia-Sciveres
11/01/22

Motivation

- Detector upgrades → more massive material
- Higher rate of data transmission requires more massive cables
- Can we modify the hardware of the ITkPixV1 to be able to transmit more data through the same cable
- Can we achieve PAM4 using CML bias?

Goal:

- Modify the chip to achieve PAM4 signal transmission as opposed to current NRZ signal transmission

NRZ

NRZ:

Non-Return-to-Zero (NRZ) is a binary code using high/low signal levels to represent 1/0 in digital logic signal. NRZ transmits 1 bit per signal level

PAM4

PAM4:

Pulse-Amplitude-Modulation level 4 (PAM4) is a signal transmission format in which each signal level can encode 2 bits of information → 4 distinct levels.

NRZ vs PAM4

NRZ and PAM4 Encoding

Example:

- Using PAM4, word 101100100100 was transmitted in half the time compared to NRZ. Higher baud rate

NRZ vs PAM4

Drawbacks of PAM4

- PAM4 amplitude is split into 3 eyes $A_{\text{PAM4}} = \frac{1}{3} * A_{\text{NRZ}}$
- Signal to Noise Ratio loss
 - $\text{SNR} = 20 * \log(A)$

PAM4 has ~9.5dB SNR loss compared to NRZ

Next steps

- Design circuit that will merge channels from Cml output and achieve a PAM4 signal output
- Consider achieving PAM4 with the CML bias

Method

- Attach resistive dividers to channel outputs to modify the amplitude of the output to get PAM4 signal
